

Chapter 14 - Protection

- [Chapter 14 - Protection](#)
 - [Definitions](#)
 - [Domain](#)
 - [Access Matrix](#)
 - [Implementation of Access Matrix](#)
 - [Global Table](#)
 - [Access List](#)
 - [Capability List](#)
 - [Role Based Access Control \(RBAC\)](#)
 - [Access Rights Revocation](#)
 - [Capability-Based System](#)
 - [Hydra System](#)
 - [Cambridge CAP System](#)
 - [Language-Based Protection](#)

1. Definitions

Protection is to ensure that only authorized processes can operate on certain resources limited to its rights.

- Protection is internal. Security is external.
- **Key Principle** of Protection is the [Principle of Least Privilege](#).

2. Domain

- Domain = Collection of Access Rights = Objects, {Right-Set}
- Protection Domain = Process + Domain = Process + (Objects, {Right-Sets})
- Domain covers [User](#), [Process](#), [Procedure](#) and [Domain Switching capability](#) (User, Kernel mode).
- Domain can be [static](#) or [dynamic](#).
- Unix Domain associates with User (instead of with process).

3. Access Matrix

Access matrix is a model of protection.

domain \ object	F_1	F_2	F_3	laser printer	D_1	D_2	D_3	D_4
D_1	read		read			switch		
D_2				print			switch	switch
D_3		read	execute					
D_4	read write		read write		switch			

Domain as Objects.
A process executing in D_1 can switch to D_2 .

Domain D_1 can switch to D_2 .

- Domain can have access rights (switch, control) to other domain.
- Access Right copy is denoted by (*), indicating the access right can be cloned to other domain in the same object.
- Owner access right allow add/remove of rights.

3.1. Implementation of Access Matrix

3.1.1. Global Table

- Simple, large table storing access rights between Domain, Object, Right-set.
- May need to use Virtual Memory for storing.

domain \ object	F_1	F_2	F_3	laser printer	D_1	D_2	D_3	D_4
D_1	read		read			switch		
D_2				print			switch	switch
D_3		read	execute					
D_4	read write		read write		switch			

Domain as Objects.
A process executing in D_1 can switch to D_2 .

Domain D_1 can switch to D_2 .

3.1.2. Access List

- Is an implementation of Access Matrix assoc with each Object.
- Base on Object, create link of Domain/User and allowed operations.
- Likely used in UNIX.

3.1.3. Capability List

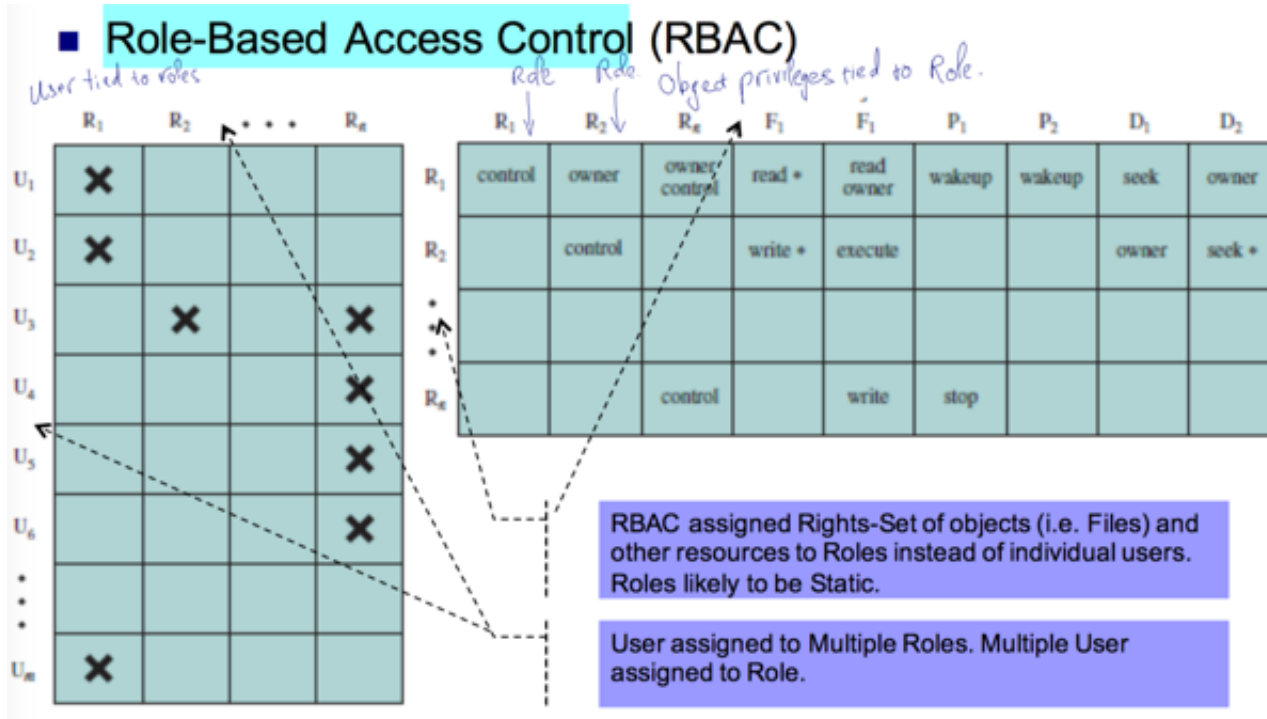

- Is an implementation of Access Matrix assoc with each Domain.
- Base on User/Domain, create link of Object and allowed operations.
- usually used for file descriptor table.

3.1.4. Role Based Access Control (RBAC)

- Is another form of Access Matrix used in Solaris, but adding concept of **Role**, and **Privileges** (Right Set).

- Role is assigned to User/Process, and privileges and objects is assigned to Role.
 - Users/Process \rightarrow Roles \rightarrow {Objects, Set of Rights}

4. Access Rights Revocation

- **Access List:** delete access rights from access list. Simple, immediate. **Revocation of Access-Rights is implemented using an Access List.**
- **Capability List:** requires to locate the capability in the system before revoking.

5. Capability-Based System

5.1. Hydra System

- Fixed set of access rights known and interpreted by the system.
- operations on Objects are through pre-defined procedures.

5.2. Cambridge CAP System

- Simpler but powerful
- Data Capability & software capability

compare Hydra & Cambridge.

6. Language-Based Protection

pros & cons
of language based
protection

- **More flexible** than the OS, but high overhead with access validation.
- Compiler-Based enforcement: restriction is built in to compiler.
- Example: **JVM** (Untrusted Classes, Stack Inspection)
